2.1 DISCRETE-TIME SIGNALS Discrete-time signals are represented mathematically as sequences of numbers. A sequence of numbers x , in which the n th number in the sequence is denoted $x[n]$, is formally written as $x = \{x[n]\}$, $-\infty < n < \infty$, (2.1) where n is an integer. In a practical setting, such sequences can often arise from periodic sampling of an analog (i.e., continuous-time) signal $x_a(t)$. In that case, the numeric value

information or signals. Signals and systems is the study of systems and their interaction. This book studies only discrete-time systems, where time jumps rather than changes continuously. This restriction is not as severe as it seems. First, digital computers are, by design, discrete-time devices, so discrete-

A discrete-time system is a device or algorithm that, according to some well-dened rule, operates on a discrete-time signal called the input signal or excitation to produce another discrete-time signal called the output signal or response. Mathematically speaking, a system is also a function.

Mathematically, system output $y(t)$ for an input signal $x(t)$ will be the convolution of that signal with an impulse signal. The output of a discrete time LTI system is completely determined by the input and the system's response to a unit impulse. System Output We can determine the system's output, $y[n]$, if we know the system's impulse response, $h[n]$, and the input, $x[n]$.

Discrete-time systems can act on discrete-time signals in ways similar to those found in analog signals and systems. Because of the role of software in discrete-time systems, many more different systems can be envisioned and [constructed] with programs than can be with analog signals.
