Drug design, often referred to as rational drug design or simply rational design, is the inventive process of finding new medications based on the knowledge of a biological target. The drug is most commonly an organic small molecule that activates or inhibits the function of a biomolecule such as a protein, which in turn results in a therapeutic benefit to the patient. In the most basic sense, drug design involves the design of molecules that are complementary in shape and charge to the biomolec

Drug design - Wikipedia

Rational Drug Design: It begins with a hypothesis that modulation of a specific biological target may have therapeutic value compared to traditional design that relies in trial-and-error. Computer-Assisted Drug Design: This methodology uses computational chemistry to discover, enhance, or study drugs and related biologically active molecules. The most fundamental goal of this methodology is to predict the binding affinity of a given molecule to a target and the associated binding kinetics.
